

Pre-Diabetes: Turn It Around

A warning sign — and one of the best chances you'll ever get to act early

Not diabetes — and you can still change the path.

Pre-diabetes means your blood sugar is higher than normal, but not yet in the diabetes range. With a few real changes, many people bring it back to normal — and protect their heart at the same time.

6.0–6.4%

HbA1c range that puts you in the pre-diabetes zone

Up to 58%

lower risk of diabetes with lifestyle change

people with pre-diabetes return to normal range

Why it matters now

A real window of time

Pre-diabetes builds quietly over years. Catching it now — before complications start — is the best moment to act.

Your heart matters too

Even at the pre-diabetes stage, blood pressure, cholesterol and heart risk are already nudging up — so changes protect more than your blood sugar.

Family history isn't destiny

Genes load the gun; lifestyle pulls the trigger. The habits you choose now have a bigger effect than your family tree.

Small numbers, big shifts

Losing 5–10% of your weight can move your HbA1c back down meaningfully — you don't need to be perfect.

What do the numbers mean?

HbA1c is your average blood sugar over about three months. Below 6.0% is normal; 6.0–6.4% is pre-diabetes; 6.5% or above is diabetes. We'll usually recheck every 6–12 months to see how you're tracking.

Your Action Plan

The changes that work, and when to come back

Six changes that move the needle

Move 30 min, most days

Brisk walking, swimming, cycling — anything that lifts your heart rate. Two short walks count just as well as one long one.

Build a little muscle

Resistance work twice a week — bodyweight, bands, or weights. Muscle uses sugar even at rest.

Smarter on the plate

Half the plate vegetables, a palm of protein, fewer refined carbs and sugary drinks. Mediterranean-style eating fits well.

Aim for a small weight loss

Just 5–10% of your current weight can shift your HbA1c — for many that's 5–8 kg, not a transformation.

Sleep & stress count

Short sleep and high stress push blood sugar up. Aim for 7–8 hours and protect some downtime.

Quit smoking — biggest single win

If you smoke, stopping protects your heart and kidneys more than almost any other change. Ask us for help.

See your doctor if you notice:

- Much more thirsty, frequent urinating, or blurred vision
- Unexpected weight loss or feeling very tired
- Symptoms that just don't feel right to you
- A new foot sore, blister, or numbness in the feet

Your next steps:

- ✓ Book a recheck of your HbA1c in 6–12 months
- ✓ Ask about a GP review and a dietitian referral
- ✓ Pick just one change to start this week
- ✓ Get the family checked — risk often runs together

A warning — and a real chance

Pre-diabetes is your body asking for a hand. Small steps now save big problems later.

You don't need to be perfect — just kinder to your body, week after week. — Dr Regu
